

Nevada Housing Affordability Survey

Housing affordability appears to be a major public concern among Nevada registered voters. Nearly all respondents describe housing costs as at least somewhat serious, including 64% who say the issue is very serious. Concern is especially high among younger voters, with 71% of voters ages 18–34 describing housing affordability as very serious compared with 48% of voters ages 65 and older.

Respondents broadly support interventionist housing policies. Restrictions on corporate or institutional homebuyers receive the strongest support, with 78% supporting the policy overall. Rent increase limits also receive substantial support, particularly among renters: 45% of renters strongly support rent caps compared with 29% of homeowners. This suggests renters are one of the clearest pro-regulation coalitions in the survey.

Support for allowing more housing is positive overall but more politically divided. Democrats are the strongest supporters of expanding housing supply, while Republicans are more likely to oppose new development. The housing tradeoff question shows a closely divided electorate: 45% prefer building more homes even if neighborhoods change, while 40% prioritize protecting existing neighborhoods even if fewer homes are built. This suggests voters recognize the need for additional housing supply but remain concerned about neighborhood impacts and development-related tradeoffs.

Methodologically, the largest limitation is that the dataset contains no weighting variable, meaning all topline and crosstabs are unweighted estimates. Before treating the results as representative of Nevada registered voters, I would benchmark the sample against known voter demographics, particularly age, education, race/ethnicity, region, and party registration. I would also caution against overinterpreting smaller subgroup differences, especially among groups with lower sample sizes. Overall, the survey provides strong directional evidence about housing attitudes in Nevada, but representativeness cannot be fully evaluated without weighting and sampling documentation.
